Monitoring

To make monitoring Webdesk EWP easier, a whole set of **tools** has been provided.
The **log settings**, for example, can be parameterized as required, so that particular actions, particular users, or log levels for particular functions are output. The log levels can be defined in different gradations as needed, for example as info, warning or error message. The logging depth affects performance, as it is quite memory-intensive.

Further monitoring tools are the display of **logged-in users**, of **active jobs**, and the **log entries**, which document which jobs ran when and with what result.
The **Status Report Cocoon** parameter gives a general overview of the status of the web application. Worth mentioning here are the memory consumption, the available memory and the JRE in use.
