Job PropagateMetaStructure

Purpose

The job synchronizes a metadata structure with the assigned document repositories by running propagation for selected repository/metadata-structure mappings.

Configuration

- **Synchronize all repositories** (selectAll): Processes all available repository/metadata-structure mappings.
- **Selection** (selectedRepositories): Processes only the selected mappings.

Behavior

- For each mapping, synchronization between the metadata structure and the repository is started and logged.
- Errors for one mapping are logged; further selected mappings are then processed.
- If the job configuration is missing, the job aborts with an error.

The mapping must already exist. The job does not create a new repository/metadata-structure mapping.
